At the 16th meeting of the Conference of the Parties to CITES (CoP16) in March 2013, **five shark species and all manta rays** were included in CITES Appendix II. The entry into effect of these listings was delayed until 14 September 2014 to resolve technical and administrative issues related to their implementation. These listings set challenges and opportunities for Parties in implementing CITES regulations for highly-traded fishery commodities.

What should CITES Parties do by 14 September 2014?

Countries wishing to (re-)export or import specimens of the recently CITES-listed sharks and rays after 14 September 2014 must meet certain requirements, for which collaboration between CITES authorities and fishery agencies is essential:

Legality: Ensure that specimens in trade have been legally acquired, through monitoring and compliance with applicable laws, (sub)regional fishery management measures, etc.

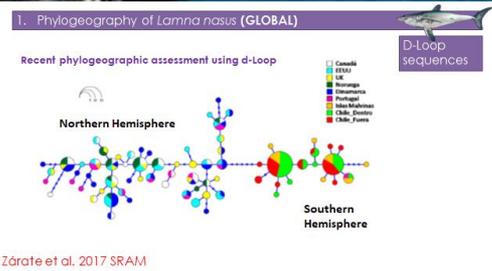

Sustainability: Determine that proposed trade will not be detrimental to the survival of the species, through scientific assessments of the status of the species in the national/regional territory (called 'non-detriment findings' or 'NDFs' in CITES).

Traceability: Record and trace trade from the country of origin to the country of destination, through the issuance of appropriate CITES permits or certificates, inclusion of all relevant trade in national annual reports and the CITES Trade Database, training of enforcement authorities on CITES regulations, identification/verification of specimens, etc.

Final Report

November 2017

We limited our analyses to the region south of 30 °S which provided most of the available data, although the porbeagle shark's range extends slightly north of this latitude. Porbeagle sharks are taken in fisheries at least as far south as 56 °S. Southern Hemisphere population structure is not well understood, and we considered it unlikely that the population comprises a single well-mixed stock for management purposes. We subdivided the spatial domain of the assessment into five subpopulations or regions by longitude: 1) Western Atlantic Ocean; 2) Eastern Atlantic/Western Indian Ocean; 3) Eastern Indian Ocean; 4) Western Pacific Ocean; and 5) Eastern Pacific Ocean.

SUMMARY REPORT

4.3.7 Porbeagle shark (*Lamna nasus*)

a. Stock status and trends

1. SC13 noted that although the stock status of the species is currently unknown the results of the assessment show that fishing mortality on the Southern Hemisphere stock is very low, and that it decreases eastward from the waters off South Africa to the waters off New Zealand. In the assessment area (Eastern Atlantic to Western Pacific Ocean) in the last decade (2005 to 2014), median F values ranged from 0.0008 to 0.0015 (mean 0.0010). This fishing mortality was less than 9% of the MIST based on r in all years assessed (1992-2014) and fell to half that level in more recent years (Figure POR-1), with at most a 3% probability of exceeding the MIST based on r in 2010-2014 (Figure POR-2). For the same scenarios, fishing mortality is less than 12% of the MIST based on $0.75r$ and less than 18% of the MIST based on $0.5r$.
2. These scenarios are based on 100% capture mortality, and assuming that some porbeagles survive their encounter with the fishery would reduce the estimated risk levels even further.

b. Management advice and implications

3. SC13 advises WCPFC14 that although the stock status of the species is currently unknown there is a very low risk that the Southern Hemisphere porbeagle shark is subject to overfishing anywhere within its range.
4. SC13 recommends that WCPFC14 request the Common Oceans (ABNJ) Tuna Project to explore options for data improvements through liaison with other regional fishery bodies managing fisheries catching Southern Hemisphere porbeagle shark.
